

The RootBeer project is a mature codebase that has moved from early feature development into long-term maintenance. Commit history indicates that the majority of meaningful work has been carried out by a single core developer, with limited but important contributions from others earlier in the project's lifecycle.

Scott Alexander-Bown (scottyab) is the primary and ongoing contributor. He has touched all core source files and accounts for the majority of commits both historically and in recent weeks. The scatter plot shows his activity spanning the entire project timeline, including the most frequently modified files. This indicates strong technical ownership and positions him as the most appropriate developer for future refactoring, security fixes, or architectural changes.

Several contributors appear only during the early weeks of the project and do not appear in later activity. These developers contributed to initial implementation but show little to no recent file touches, suggesting they have left the project rather than being temporarily inactive. Instead, their activity is clustered near week zero in the scatter plot and limited to a small number of files, suggesting targeted contributions rather than ongoing ownership. This pattern is consistent with short-term contributors or collaborators rather than long-term maintainers.

The primary project risk is key-person dependency. With nearly all recent work handled by one developer, continuity depends heavily on that individual's availability. From a management perspective, adding a secondary maintainer or improving internal documentation would reduce long-term risk.

This analysis was supported using standard Git workflows. The necessary repositories were retrieved using git clone, and branching (git branch, git checkout) enabled safe analysis without impacting the main code line. Furthermore, the use of git add, git commit, and git push to successfully track and upload all changes on the new branches to the remote github repository.
